## 6 Abstract

7 Zayandeh Rood Basin, Iran is a basin with many environmental hazard threats. In last years,  
8 analysts have concentrated on building an extent of strategic responses to raise the ability of  
9 communities and businesses to control and meliorate from natural catastrophes. The experiment  
10 from each new tension adds further to the procedure of risk management. This article inspects how  
11 they belayed for, and recuperated from, the incident. Perhaps not astonishingly, it represents their  
12 exposures and absence of readiness for dealing with a risk of this dignity. Then again, it proves the  
13 resilience of real-world managers and their confidence on an aggregate experiment to operate their  
14 own improvement. In periods in which hazard management has been under drastic press to indicate  
15 effectiveness and cost efficiency. These threats function in environmental disasters with terrible  
16 reaction such as damage of human properties, disruption to human livelihood activities and the  
17 bother imposed on economy. So, hazard management is essential for solution these repercussions.  
18 Moreover, multi hazards are associated with desertification, earthquake, and aridity, similar any  
19 other nation, Iran is imperiled by many environmental risk menaces and such menaces can peak  
20 in environmental catastrophes with massive reactions such as loss of people's lives, destruction of  
21 national assets, an outage of a man-made building, dangers overhanging mass population, etc. In  
22 this case, the integrated approach uses the Arc GIS to create individual map layers that describe  
23 the spatial distribution of a parameter describing the intensity of the hazards. In this study, the  
24 intensity of the hazards threat is classified into 5 classes based on scale. In last years, increasing  
25 population and development of settlements and life-lines over perilous zones have mostly  
26 increased the effect of natural catastrophes both in industrialized and developing countries. The  
27 classes and range values include 'very high', 'high', 'moderate', 'low' and finally 'very low'. As  
28 the study area, the Zayandeh Rood Basin (Z.R.B) was selected into 10km grids. The parameters  
29 explain the hazard threats, their areal extents and densities, were determined for each grid. So,  
30 each layer map of a particular hazard and risk layer shows the spatial distribution of that particular  
31 hazard threat. In this research, each layer of the hazard threat and risk map was integrated using  
32 the Arc GIS integration analysis based on parameters. More importantly, the SWAT analysis shows  
33 the spatial distribution based on parameters of hazards and risk parameters in a grid cell, as well  
34 as showing the basin as the table whole that could result in efforts made to alleviate many hazards  
35 in the future. This approach in hazard management assessment would significantly contribute to  
36 any efforts associated to develop early warning systems incorporating hard and soft measures in a  
37 high- and very high-intensity hazard threat areas. This article evaluates some of the items relevant  
38 to the performance of diverse GIS conveniences with respect to terrain-related risks dominant in  
39 Isfahan, with specific reference to landslides.

## 44 I. INTRODUCTION

45 Integrated Assessment (IA) is an interdisciplinary process comprised of combining, interpreting  
46 and communicating knowledge, in such a way that all the causes and effects in a problem can be  
47 evaluated from a synoptic perspective with two characteristics: (i) it needs to incorporate an  
48 added value compared to single disciplinary assessment; and (ii) it needs to provide decision  
49 makers with useful information .Jeroen (2002). Rotmans, J., et al, (1997).

50 Environmental risks at a location in space and time is not the function of a single threat parameter  
51 but is determined by many parameters. Some threat parameters exhibit less risk while others higher  
52 risks, but a cumulative value of all threat parameters provide a more exact state of risk for a  
53 particular location in space and time. The challenge here is to determine what constitute the  
54 pertinent threat parameters of a location. This study identifies 4 main environments threat  
55 parameters that could exact risks in a particular location. The threat parameters are, (1) earthquake  
56 potential, (2) desertification and (3) Aridity. Each of these threat parameters constitutes an  
57 individual layer of hazard threat and when combined through an integration process a composite  
58 hazards threat for a particular location is determined by integrating the composite hazard threat  
59 and inherent risks in that location. This defines the integration and multi- layer analysis of risks of  
60 the study.

61 Risk can be defined as a function of hazard probability and vulnerability, the latter resulting from  
62 a combination of exposure and ability to cope [15]. In addition, mapping, as well as assessment,  
63 of hazard vulnerability has frequently been overlooked in favor of hazard modeling studies Freire  
64 S. & Aubrecht C, (2012).

65 As Ayala. Alca'ntara Ayala, Irasema Alca'ntara,(2002)puts, natural hazard threats, vulnerability, and  
66 prevention of natural disasters are frequent phenomena in developing countries. Julie et al. Julie  
67 Wilk et al, (2013) explained integrated vulnerability assessment by GIS calculating. Vishwa et al.  
68 and Freire and Aubrecht Freire S. & Aubrecht C, (2012) applied seismic and vulnerability in  
69 Himalaya by a weighted average method. In addition, Merrett and Chen applied GIS and RS in  
70 natural disasters hazard assessment.

71 Fadly U, and Keisuke M applied SWAT (Strength, Weaknesses, Opportunity and Threat) uses  
72 analysis in GIS for reducing tsunami disaster by using costal vegetation plans. This model is used  
73 to identify the organization's internal strength and weaknesses with respect to the threat and  
74 opportunities of the external environment.

75 Internal and external factors: The strength and weakness are internal factors:

76 • Strengths are the attributes of the organization that are helpful to achieve the aims.

• Weaknesses are attributes of the organization that are harmful to achieve the aims. External factors: The opportunities and threat presented as external factors:

• Opportunities are the external factors which are helpful to achieve propose.

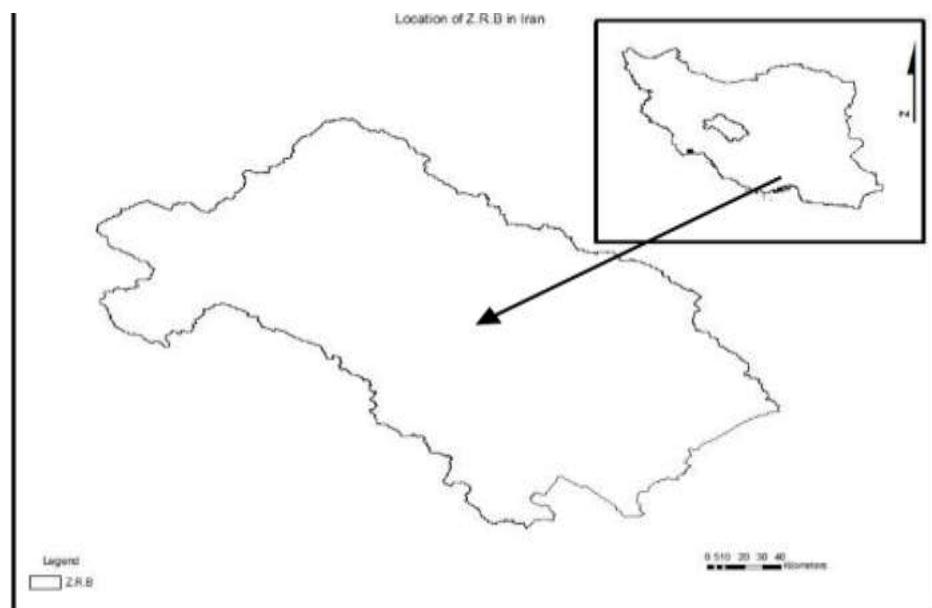

• Threats are the external factors which are harmful to achieve propose.

| SWOT ANALYSIS   |             |          |
|-----------------|-------------|----------|
|                 | Helpful     | Harmful  |
| Internal Origin | Strength    | Weakness |
| External Origin | Opportunity | Threat   |

FIGURE1. SHOWS THE ILLUSTRATIVE DIAGRAM OF SWOT ANALYSIS

## II. STUDY REGION

The Zayandeh Rood Basin is located in the central part of Iran, with geographical coordinates between  $50^{\circ} 24'$  to  $53^{\circ} 24'$  north longitudes and  $31^{\circ} 11'$  to  $33^{\circ} 42'$  north latitude. The basin approximately covers an area of 42,000 km<sup>2</sup>. Figure 2 shows the position of this basin on the map. There is more than one hazard in Z.R.B which is tectonic activities such as the earthquake, desertification and drought. On the other hand, human activities such as using land include land use, population, and strategic situation especially in the largest city of the basin, Isfahan.

۹۸

## FIGURE 2. LOCATION OF Z.R.B IN IRAN

۹۹ In this study, risk hazard map will be provided for Z.R.B in Iran by using Arc map 10.1  
۱۰۰ Classification and composite methods were used to derive a composite hazard map of classified  
۱۰۱ hazards map (Earthquake, desertification, Aridity) and human activities.

۱۰۲ Geomorphological processes caused geomorphological hazards in Z.R.B, including tectonic  
۱۰۳ activities, such as convergence of the Arabian and Eurasia plate locations. Fault types were the  
۱۰۴ main cause of earthquake in Z.R.B. Desertification hazard parameters of climate parameters, land  
۱۰۵ use, geographical location and geomorphological landform were recognized as the causes of  
۱۰۶ desertification in this area Maryam M. B. and Khairulmaini, O.S (2016).

۱۰۷ The maximum precipitation of the basin occurs during winter in January and February, while the  
۱۰۸ minimum is during summer in July and August. The average annual precipitation is 105.84 mm,  
۱۰۹ the average annual temperature is 14.9°C and the average evaporation is 2219.3 mm. The wind  
۱۱۰ erosion in the area shows the orientation of powerful winds blowing from west to southeast and  
۱۱۱ an average wind speed is 3.5 m/s [6]. The most important factors in the drought in the study area  
۱۱۲ are geographical location, no normative exploitation of the surface mineral of gypsum, non-  
۱۱۳ normative exploitation of land, reduced entrance runoff from upstream regions, a sharp drop in the  
۱۱۴ groundwater level, winds and storms laden with chalk, dust and suspended particles, low  
۱۱۵ precipitation and high evaporation.

۱۱۶

### ۱۱۷ III. MATERIALS AND METHODS

۱۱۸ The methodological framework which is appropriate for an integrated hazard assessment consists  
۱۱۹ of 3 major steps such as multi- hazards parameters, composite risk map and SWOT analysis, as  
۱۲۰ illustrated in Figure 3. In the present research, 3 component hazards, namely earthquake,  
۱۲۱ desertification, aridity have been formulated. The hazard components' parameters depend on the  
۱۲۲ characteristic of each hazard component.

۱۲۳ The following flowchart shows parameters of earthquake, desertification, aridity hazards and  
۱۲۴ classified human activities in the study area. The flowchart also shows the combination of hazards  
۱۲۵ as composite classification hazard and density human activities maps for getting the final map as  
۱۲۶ risk map Figure 3.

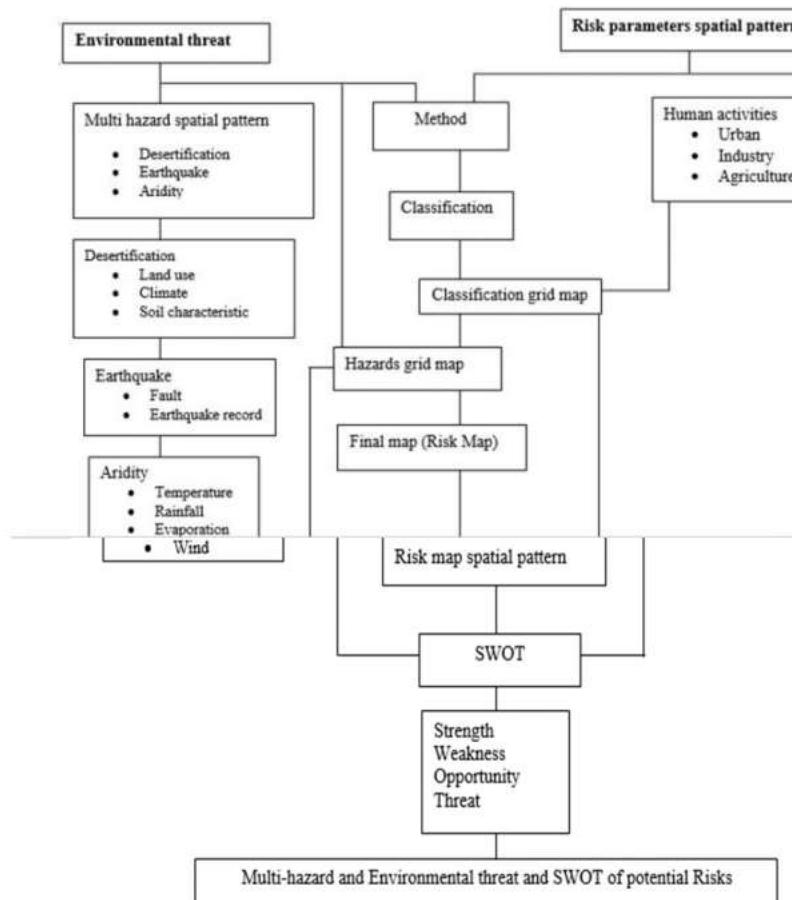

FIGURE 3. MULTI-HAZARD ENVIRONMENT THREAT ASSESSMENT PROCESS

#### IV. MULTI- HAZARDS PARAMETERS

In this paper of study investigate each parameter of hazards. The dataset for each hazard is included factors of the hazards. Classification of each factor was based on scoring and in GIS environment.

Investigation of parameters classified desertification hazard map

The following section will explain the parameters for the classified vectors and raster for the classified desertification hazard map:

Soil: In desert area, soil loss plays an important role in increasing the desertification rate. Soil temperature, soil organic matter, soil slope and soil depth play their roles in desert ecosystems. In this study, the soil dataset was used for soil characteristics such as depth, texture and parent soil. The soil information was extracted by using a vector map. The soil depth and texture were classified in the GIS environment. Tables 3 show the classes of soil characteristics in this study. The soil information was collected by using the reviews of the studies of Natural Resources Organization of Iran] Marani Barzani, M.O S Khairulmaini, (2013).

144 Climate quality: Climatic factors such as wind, evaporation, precipitation and temperature are  
145 important factors for the development of deserts in arid and semi-arid areas. A climate quality map  
146 was classified on the annual precipitation and potential for evaporation by climatologic  
147 organizations] Maryam M. B., Khairulmaini, O.S (2014)

148 Land use: One of the direct effects of factors responsible for desertification and land degradation  
149 is land use. Land use is a function of human activities. In Z.R.B, since the climate and topography  
150 are different, land use differs. In this study, land use classification was reclassified based on the  
151 purpose of study Maryam M. B. and Khairulmaini, O.S (2016)

152 Parameters were classified based on the preview models. The sum of the factors serves as an  
153 indicator for level classification. Grid map were used as a base map for scoring. The scores were  
154 calculated and then using a weighted average, all the factors were calculated.

155 The weighted average of the figures obtained from the factors within each grid as well as the  
156 classified parameters used for weighing were evaluated in a polygon attribute table and displayed  
157 as classification hazard maps (Figure 6).

158 Investigation of parameters classified earthquake hazard map.

159 Classification earthquake hazard map has been provided by carrying out earthquake parameters  
160 which are fault line, earthquake point, magnitude, depth and boundary of tectonic plate in GIS  
161 environment. Classified earthquake hazard map (Figure 7) shows five level of the hazard in Z.R.B.  
162 Based on calculating the earth quake parameters, highest class of hazard are located on South,  
163 North-west and East part of the basin.

164 This step focuses on classification of parameters based on the range of attributes, scoring of the  
165 parameters, the sum of the scores and analysis interpolation. The ranges of parameters have been  
166 shown in table (1). Classifying the magnitude comprises five classes with a range of (2. 6 - 4. 6).  
167 The range of scores for the magnitude is 0-25 and the depth with five classes (6 -51) and the range  
168 of depths is 25-0. The classified faults are based on types of fault in the area. Classification of the  
169 fault line map with respect to three types of fault are fault thrust, major and minor and the range  
170 of fault types is 1-3 .Classification parameters were calculated based on scoring the parameters for  
171 attributes and the sum of the scores, Marani Barzani, M.O S Khairulmaini, (2013).

172 Investigation of parameters classified Aridity hazard map some parameters are common between  
173 components. For example, Aridity component parameters are climate quality that they are common  
174 in desertification component also. Multi-Hazard Systems and Risk Map.

175 In order to measure each parameter in 10 (Km2) grids map would recognize parameters unit the  
176 parameters were measured for each grid (Km2) and subsequently the map was classified into 5  
177 classes of 'very high', 'high', 'moderate', 'low' and 'very low'. This method has been implemented  
178 to all the parameters of hazards and human activities, too.

179 Classified earthquake, desertification, aridity hazard maps, and classified human activities maps  
180 are the datasets for integrated hazards map and risk assessment. These datasets consist of a series  
181 of scoring and summing factors of the hazards and human activities parameters. These

classification hazards maps were provided by scoring and weighted sum estimation. The following Figure 4 shows part of grid maps and formulate that use for classification hazards parameters in the grid map. The following part will explain the calculation of a GIS-based integrated assessment framework for the case of the present study.

In this study, sum of the factors represents level classification. Use was made of Grid map as a base map for the scoring. The scores were obtained and then, using a weighted average, all the factors were calculated. The weighted average of the figures obtained from the factors within each grid section, as well as the classified parameters used for weighting, were evaluated in a polygon-attribute table and displayed as classification hazard maps (Figure 4).

The GIS-based integration assessment framework was used for the measurement of how places were influenced by hazards. This framework is based on a number of various parameters expressing physical hazards (i.e. exposure). These are combined into a common index on exposure with an index for risk map.

Figure 4 shows the GIS-based a part of Integrated Assessment Framework for the Z.R.B hazards ('very high', 'high', 'moderate', 'low', and 'very low'). Earthquake hazard 1: MS, Fault, and seismic depth; Desertification 2: Land use, climate quality, Soil characteristic; Aridity 3: Climate Parameters (Temperature, Rainfall, Evaporation, and wind). In order to measure hazard parameters, grid map (km<sup>2</sup>) is considered as a base map for measuring each parameter by Fn (x<sub>i</sub>+x<sub>i</sub>+x<sub>i</sub>...):

$$\text{Hazard parameters} = \frac{f_n(x_i+x_i+x_i+x_i)}{A}$$

Where x is scoring of each parameters' classes and A is area of each grid

FIGURE 5. THE GIS-BASED INTEGRATED RISK ASSESSMENT FRAMEWORK

## V. INTERPRETATION AND DISCUSSION

218 Multi-hazard Spatial Pattern Desertification: Almost half of the area is made up of desertification  
219 47.321% of 42000 km<sup>2</sup>. The area is a high arid area. Desertification accrues in this part of the area  
220 and the hazard is distributed among all the regions of Z.R.B. The area is inhabited by one eighth of  
221 the Z.R.B population. It is here where soil is especially fragile, vegetation is spared and climate is  
222 unpleasant and where desertification occurs. So desertification imposes damages on the half of the  
223 total land area of Z.R.B.

224 Direction of desertification has widened from eastern part of Z.R.B toward the center (Isfahan  
225 city) and the north.

226 The directions of desertification in Z.R.B were assigned to factors such as Soil, land use, and  
227 climate.

228 The desertification database of this study showed soil characteristic, climate quality, and land use  
229 in Z.R.B. Figure 6 show that desertification is increased with the decrease of vegetation in low  
230 slope area. Based on the classification desertification map, desertification intensity class is critical  
231 for the whole Z.R.B (Figure 6).

232 Results of desertification spatial direction show that most desertification was clustered around the  
233 center (Isfahan city).

THE CLASSIFIED MAP SHOWS FIGURE 8. FIVE CLASSES OF ARIDITY HAZARD MAP WHERE THE LARGE PART OF THE AREA ARE LOCATED ON NORTH AND EAST PART OF THE BASIN

Aridity: The aridity maps prepared using the classified models show that there are instances of arid, semi-arid, dry and sub-humid zones in the area under the present study. A greater part of the area of Z.R.B. is covered by the semi-arid class, except for some parts in the north-western end, which belong to the humid class. The central, eastern and north of Z.R.B. is covered by the semiarid and arid classes with high temperature, evaporation, the wind and low rainfall. The total annual evaporation in this region is also higher than or equal to the annual rainfall (Figure 8).

The mean annual evapotranspiration in this region is four times higher than the mean annual rainfall. It can be seen that the climate of 25.14% to 32.5% of Z.R.B. has been identified by different aridity index models as being near hyper-arid, from 55.59% to 80.44%, it is demarcated as the acriest, 7.82% of the area is semi-arid 9.34% of the area is sub-humid and less than 1.55% of the area as humid. Maryam M. B. and Khairulmaini, O.S (2017)

#### Risk Parameters Spatial Pattern

Human activities: In this research, human activities refer to urban, industrial and Agriculture for risk map. There are special strategic situations in the study area. The majority of parameters concentrate on Center, West, South and West-North of the area (Figure 9). In Z.R.B, the majority of the population resides in the Center of the basin. The high and very high population's classes reside in the city of Isfahan. The highest centers of agricultural land are located in the center of Z.R.B. There are a lot of plain lands in the city of Isfahan.

۳۳۴

۳۳۵

۳۳۶

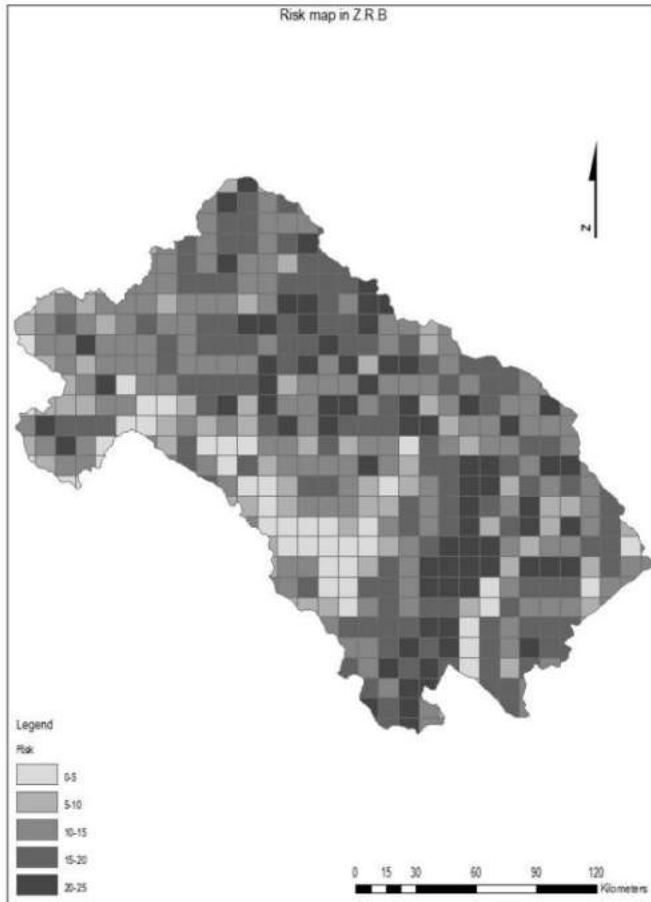

FIGURE 9. CLASSIFIED HUMAN ACTIVITIES MAP IN Z.R.B

۳۳۷

Risk Density: Risk map which is the combination of classified hazards map and classified human activities. In order to make risk map, the integrated assessment hazards of layers are important.

۳۳۹

Figure 10 shows grid analysis based on weighted average. Each factor has measured in each grid based on the unit. Then each factor classified in five classes and according to significant of the factors weighted average and reclassified. After this any hazard map classified and each grid was compared between the two hazards and human activities map.

۳۴۳

۳۴۴

FIGURE 10. CLASSIFIED RISK MAP IN Z.R.B

۳۴۵

Results showed multi-hazards, land use, risk clusters and percentage area for each class. High classes of risk area are 9198.93 km<sup>2</sup> that is 21.9642 of the whole basin area. The maturity of risk is located in the north, west and east of Z.R.B. High classes of risk area are around human activities in the basin area (Table 1).

TABLE 1. DISTRIBUTION OF HAZARD CLASSES AREA AND PERCENTAGE IN Z.R.B

According to frequency and intensity of the desertification and aridity occurring in the area, a qualitative hazard assessment was carried out which enabled mapping of areas that might be affected by events of different classes. Elements at risk from future human activities in North and East of the area were identified. Five levels of risk (i.e. very low, low, moderate, high and very high) were detected and mapped. The areas at high risk were determined by aridity of lands with high hazards and high vulnerability conditions (resident and transport infrastructures). Areas of lower risk were identified on the basis of a lower occurrence probability and lower vulnerability linked only to eastern parts of Z.R.B (Table 2).

TABLE 3. SWAT ANALYSIS FOR RISK ASSESSMENT IN Z.R.B

۳۹۱

The inferences of the SWAT analysis (Table 3) are as under:

۳۹۷

A high population density, high residential density, moderate industrial, moderate agriculture is impacted for the risk in the event. Disaster management planning is an ongoing process for the threat events in the area. There is needed to make use of the strengths for converting the threats, weakness and opportunities in to improve strengths.

۴۰۱

## VI. CONCLUSION

۴۰۲

An integrated multidisciplinary approach to assessing desertification, earthquake, aridity hazards applied in this research, including geomorphological, geo-structural and meteoroidal showed the hazards and risk have significantly increased in last decades. Since 30 years ago, growing population and human activities, desertification hazard also occurred while during the time earthquake event without any damages for human activities in Z.R.B. Furthermore, aridity hazard has gradually increased both in terms of frequency and magnitude. There is enhancing regard global about the ineffectiveness of prevalent drought management practices that are mostly depended on risk management. These functions are reflexive and, thus, only act the signs (effects) of drought rather than the underlying causes for the vulnerabilities related with effects. Via the assumption of public drought diplomacy that are focused on risk decrement and accompany by drought mitigation or preparation projects at different levels of government, the coping inclusion of nations to operate droughts can be amended. This article considers the underlying implications of drought, the principles and objectives of national drought diplomacy and a drought planning procedure that has been impressive in the procurement of drought mitigation projects. The perils related with these variations are actual but extremely unknown. Perils are outward in agriculture, fisheries and many other parts that organize the subsistence of rural populations in enlarging countries. This evolution seems to be due to a recent meteoroidal trend consisting of changes within distribution of yearly precipitation and high temperatures in the area. However, the yearly average rainfall decreased during the last decade.

۴۲۱

Due to the increase of hazards and concerning the growth of human activities including buildings, industries, strategic planning in the area, the risk conditions were analyzed in order to achieve a risk zonation and to propose strategies for mitigating against them by management planning. The high-risk area is characterized by a high level of the hazards and this is due to the possible development of desertification, aridity and, the last but not the least, vulnerability. This is important for countries like Iran which are exposed to many threats acting on dame locality. This knowledge provides a basis for sound development planning that's focus on existing hazards at a locality in space. This work is intended to policy maker, planner disaster manager, environmental conservation group, private citizen that use available mitigation tools and technique to decrease the vulnerability of hazards. By following the multi hazards assessment a government can create an effective policy for mitigating the impact of natural hazards.
